Medical Progress

BRONCHIECTASIS

ALAN F. BARKER, M.D.

This affection of the bronchia is always produced by chronic catarrh, or by some other disease attended by long, violent, and often repeated fits of coughing.

R.T.H. Laënnec[1]

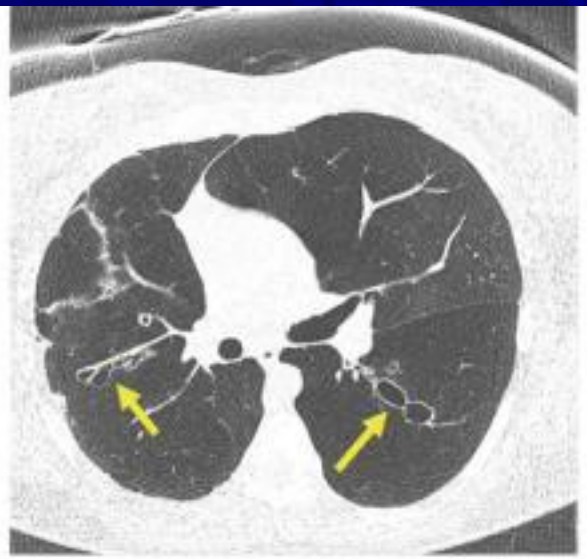
BRONCHIECTASIS is an uncommon disease with the potential to cause devastating illness, including repeated respiratory infections requiring antibiotics, disabling productive cough, shortness of breath, and occasional hemoptysis. Landmarks in the history of bronchiectasis include the vivid descriptions of patients with suppurative phlegm that appeared in the writings of René Théophile Hyacinthe Laënnec in the early 19th century; the 1922 introduc-

dilated airways alone and is sometimes seen as a residual effect of pneumonia; varicose bronchiectasis (so named because its appearance is similar to that of varicose veins) is characterized by focal constrictive areas along the dilated airways that result from defects in the bronchial wall; and saccular or cystic bronchiectasis is characterized by progressive dilatation of the airways, which end in large cysts, saccules, or grape-like clusters (this finding is always indicative of the most severe form of bronchiectasis).[2]

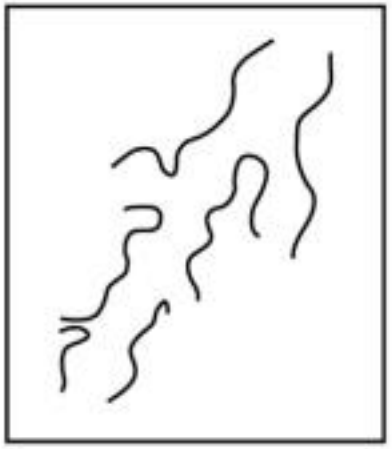
The prevalence of bronchiectasis in the United States and worldwide is unknown. There are reports of high prevalence in relatively isolated populations with poor access to health care and high rates of respiratory tract infections during childhood, such as Alaskan Natives in the Yukon–Kuskokwim Delta.[3]

PATHOPHYSIOLOGY

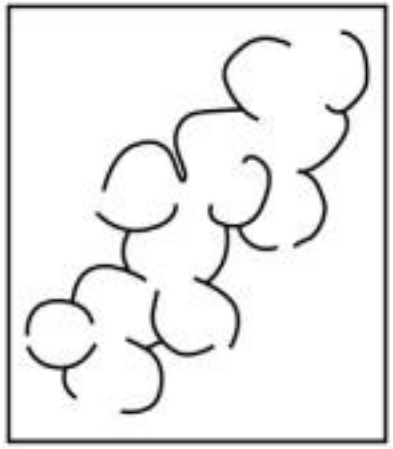
Bronchiectasis is primarily a disease of the bronchi and bronchioles involving a vicious circle of transmural infection and inflammation with mediator release.[4] Illness is related to retained inflammatory secretions and microbes that cause obstruction and damage



Cyclindrical

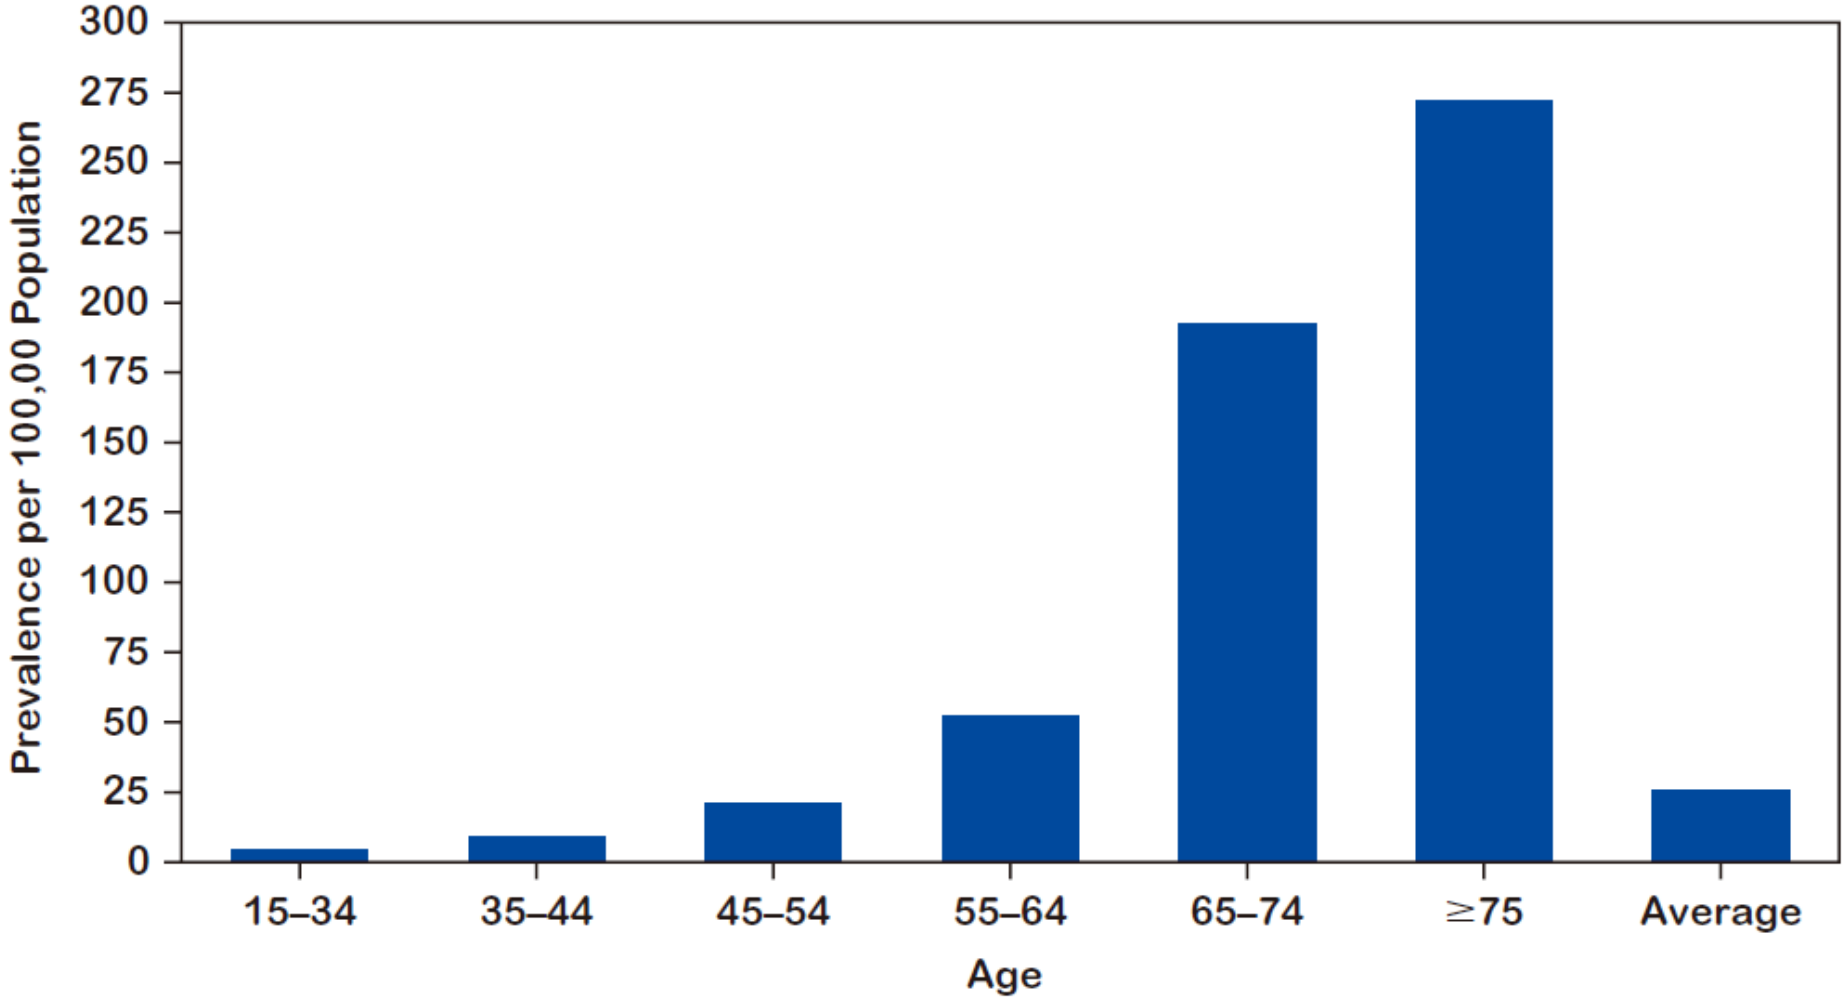


Varicose



Cystic

Prevalence of Bronchiectasis



Bronchiectasis increases with age. It is likely to be much more common than reported here because it is not usually detected, reported, or treated (2).

Changes in the incidence, prevalence and mortality of bronchiectasis in the UK from 2004 to 2013: a population-based cohort study

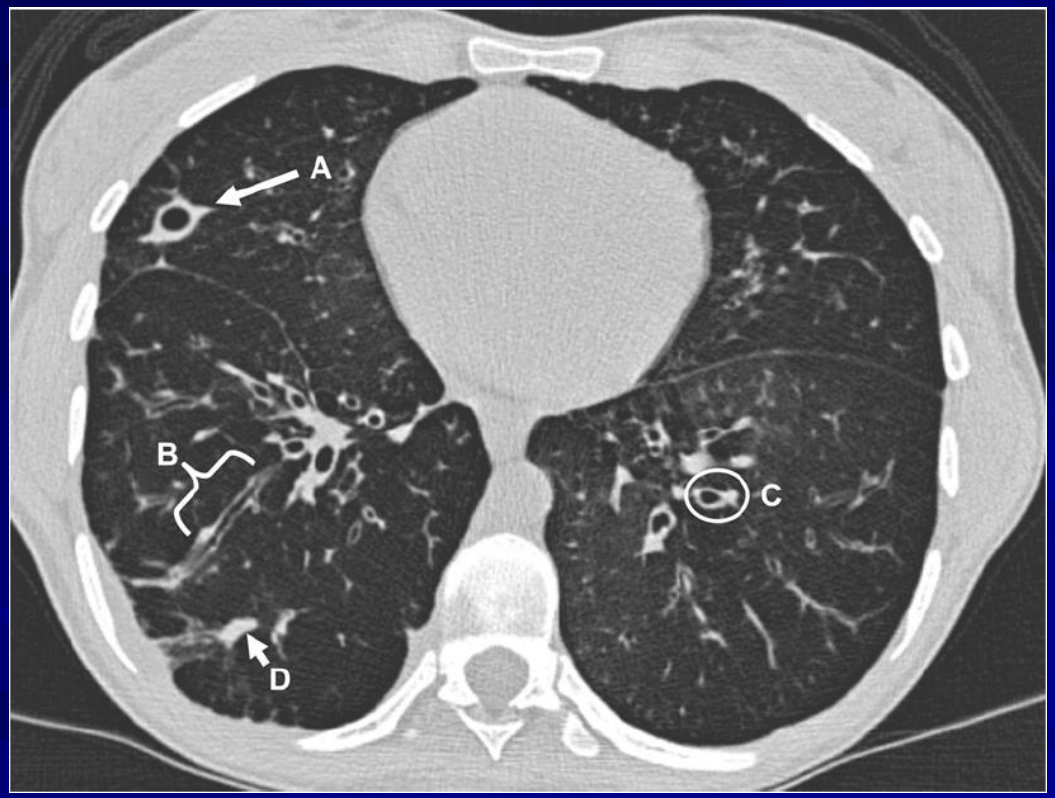
Chandrasekaran et al. BMC Pulmonary Medicine (2018) 18:83

Diagnosis : HRCT



Radiographic signs of BE.

A . Bronchus terminating in a cyst;

B . lack of bronchial tapering as it travels to the periphery of the lung;

C . signet ring sign (bronchus is larger than the accompanying vessel);

D . mucus plug (mucus completely filling the airway lumen).

Outline

- Introduction
- The assessment of Non-Cystic Fibrosis Bronchiectasis (Non-CF BE)
- Management approach
- Summary

ETIOLOGY

- Idiopathic
- Congenital and structural abnormalities of the tracheobronchial tree (bronchial wall defects or abnormalities such as tracheomegaly and polychrondritis)
- Bronchial obstruction
  - Intrinsic (post-TB stenosis, foreign body, benign tumour, etc.)
  - Extrinsic (tumour or lymph node compression)
- Gastroesophageal reflux
- Granulomatous diseases (sarcoidosis, TB, etc.)
- Traction (pulmonary fibrosis of any cause including fibrosing alveolitis and severe acute respiratory syndrome)
- Immunodeficiency
  - Primary (pangammaglobulinaemia or selective immunoglobulin deficiency, including IgG subclass deficiency)
  - Secondary (acquired immune-deficiency syndrome or malignancy)
- Diffuse panbronchiolitis
- Primary ciliary dyskinesia (including Kartagener's syndrome)
- Post-infection (TB, pertussis, measles, etc,)
- Post-necrotising pneumonia (Klebsiella pneumoniae, Staphylococcus aureus, etc.)
- Atypical mycobacterial infection
- Allergic bronchopulmonary aspergillosis
- Post-transplantation (heart-lung, lung and bone marrow)
- Miscellaneous (yellow nail syndrome and alpha-1-antitrypsin
- deficiency, etc.)

Risk factors for morbidity and death in non-CF BE: a retrospective crosssectional analysis of CT diagnosed BE

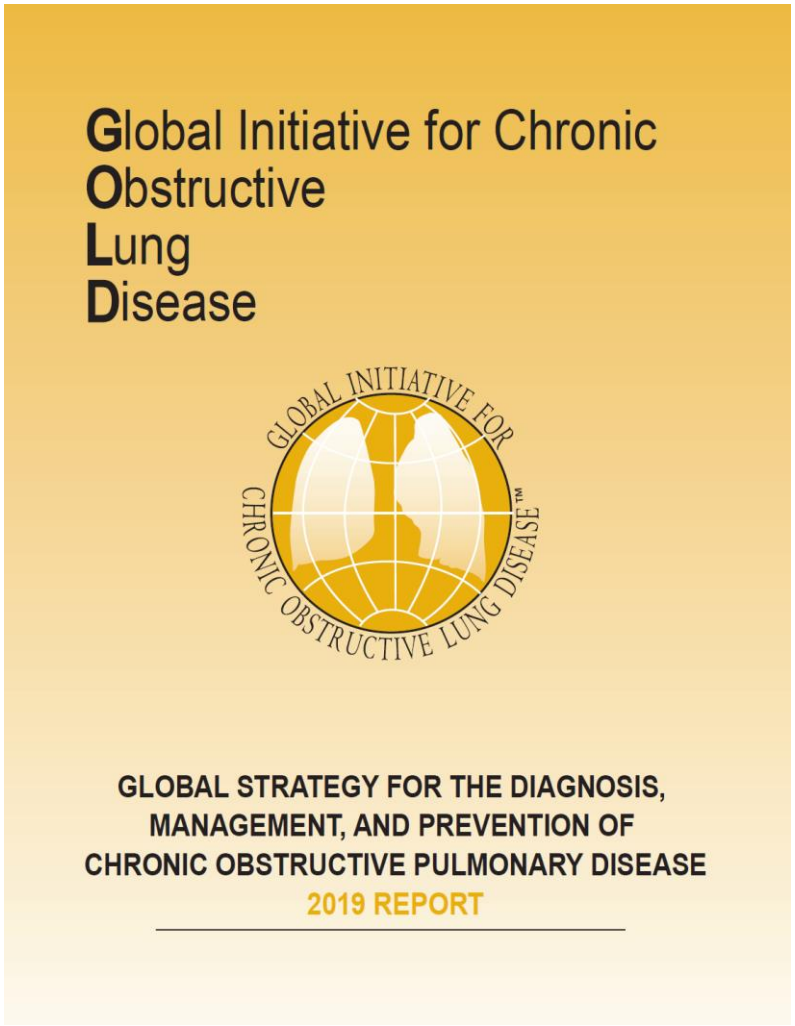
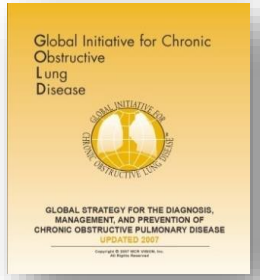
GOLD 2019 Report: Chapters



1. Definition and Overview
2. Diagnosis and Initial Assessment
3. Evidence Supporting Prevention & Maintenance Therapy
4. Management of Stable COPD
5. Management of Exacerbations
6. COPD and Comorbidities

Exacerbations

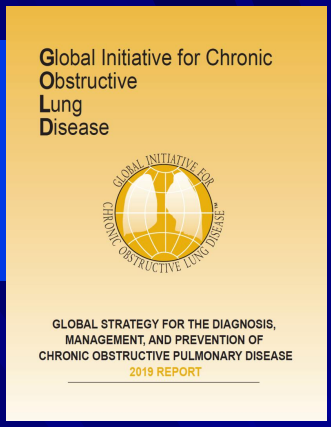


COPD Comorbidities

- **Cardiovascular disease**
  - Major comorbidity, Most frequent, Most important
- **Bronchiectasis**
  - Longer exacerbation and increased mortality
- **Metabolic syndrome and Diabetes**
- **Osteoporosis**
- **Anxiety and Depression**
  - Major comorbidities
    Under-diagnosed
    Poor health status and Prognosis
- **Lung cancer**
  - Frequently in COPD
    Most frequent cause of death in mild COPD
- **Infections**

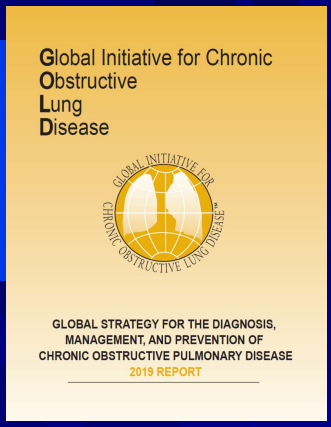
GOLD 2014 - Should be actively looked for and treated appropriately if present

GOLD report 2019



- With increasing use of CT in the assessment of patients with COPD, the presence of previous unrecognized BE is being identified.
- Whether this diagnosis on radiological criteria has the same impact as a clinical diagnosis of BE remains unknown at present, although it is associated with longer exacerbations and increasing mortality.

GOLD report 2019



- BE should be treated according to usual guidelines

- Regarding COPD treatment, some patients may need more aggressive and prolonged antibiotic therapy. Inhaled corticosteroids may not be indicated in patients with bacterial colonization or recurrent lower respiratory tract infections.

The impact of Non-CF BE on Asthma

Overlap of asthma and bronchiectasis

- Both 2 diseases are of heterogeneity in clinical presentation and outcome
- How could Asthma lead to BE?
  - Recurrent infection → bronchiectasis
  - MMPs imbalance → tissue destruction?
- Bronchiectasis + asthma: 3-8%
- Severe asthma + bronchiectasis: 25-80%

Polverino et al, "The overlap between BE and C.A.D." ERJ 2018; 52: 1800328

Bronchiectasis in asthma

- Consequence of long-lasting, severe, uncontrolled asthma
  - Non-allergic asthma
  - Immunodeficiency from chronic steroid therapy
  - Poor response to high-dose ICS and recurrent infectious symptoms; neutrophilia in sputum
- ABPA: should be identified due to fair response to systemic steroid therapy and anti-fungal treatment

Asthma in bronchiectasis

- Potential influence of asthma on the management and prognosis of bronchiectasis is **unclear**
- Hard to identify asthma in bronchiectasis
  - Asthma-like symptoms could be reported in stable diseases
  - Best biomarker to differentiate under discussion

Asthma in bronchiectasis

Abstract

Rationale: Allergic sensitization is associated with poor clinical outcomes in asthma, chronic obstructive pulmonary disease, and cystic fibrosis; however, its presence, frequency, and clinical significance in non–cystic fibrosis bronchiectasis remain unclear.

Objectives: To determine the frequency and geographic variability that exists in a sensitization pattern to common and specific allergens, including house dust mite and fungi, and to correlate such patterns to airway immune-inflammatory status and clinical outcomes in bronchiectasis.

Measurements and Main Results: A high frequency of sensitization to multiple allergens was detected in bronchiectasis, exceeding that in a comparator cohort with allergic rhinitis ($n = 149$). Sensitization was associated with poor clinical outcomes, including decreased pulmonary function and more severe disease. "Sensitized bronchiectasis" was classified into two immunoallertypes: one fungal driven and proinflammatory, the other house dust mite driven and chemokine dominant, with the former demonstrating poorer clinical outcome.

Outline

- Introduction
- The assessment of Non-Cystic Fibrosis Bronchiectasis (Non-CF BE)
- Management approach
- Summary

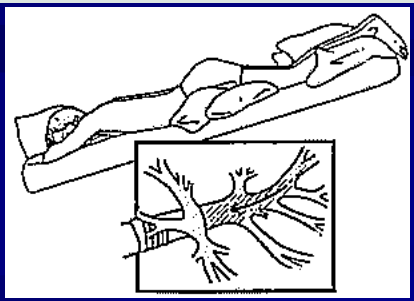
Summary of recommendations from the ERS guidelines for management of adult bronchiectasis

	Strength of recommendation	Quality of evidence
Do a minimum bundle of tests, including differential blood count, serum immunoglobulins, and testing for ABPA in newly diagnosed patients	Conditional	Very low
Treat acute exacerbations of bronchiectasis with 14 days of antibiotics	Conditional	Very low
Patients with a new isolation of *Pseudomonas aeruginosa* should be offered eradication antibiotic treatment	Conditional	Very low
Do not offer eradication antibiotic treatment to patients after new isolation of pathogens other than *P aeruginosa*	Conditional	Very low
Do not offer inhaled corticosteroids for the treatment of bronchiectasis	Conditional	Low
Do not offer statins for the treatment of bronchiectasis	Strong	Low
Offer long-term antibiotic treatment for patients with three or more exacerbations per year*	Conditional	Moderate

James D Chalmers, Lancet Respir Med 2018; 6: 715–26

Summary of recommendations from the ERS guidelines for management of adult bronchiectasis

Offer mucoactive treatment for patients with difficulty expectorating sputum and poor quality of life when standard airway clearance techniques have failed to control symptoms	Conditional	Low
Do not offer recombinant DNase for the treatment of bronchiectasis	Strong	Moderate
Do not routinely offer long-acting bronchodilators for patients with bronchiectasis	Conditional	Very low
Offer long-acting bronchodilators for patients with clinically significant breathlessness on an individual basis	Conditional	Very low
Do not offer surgical treatments, except to patients with localised disease and high exacerbation frequency despite optimum medical care	Conditional	Very low
Patients with chronic productive cough or difficulty expectorating should be taught airway clearance techniques	Conditional	Low
Patients with impaired exercise capacity should participate in pulmonary rehabilitation and take regular exercise	Strong	High



James D Chalmers, Lancet Respir Med 2018; 6: 715–26

Treatable traits in bronchiectasis

Treatable (therapeutic) traits

Chronic airway infection
- Antibiotic therapy
  - Inhaled
  - Targeted
  - Macrolides

Pathogen acquisition
- *Pseudomonas aeruginosa* eradication therapy

Immunodeficiency
- Immunoglobin replacement
- Prophylactic antibiotics

NTM
- Antibiotic therapy

ABPA
- Corticosteroids
- +/– antifungals

Airflow obstruction and functional impairment
- Pulmonary rehabilitation
- Bronchodilators

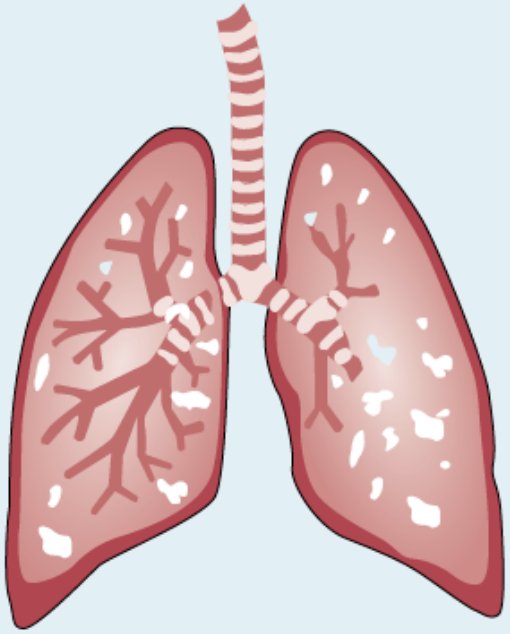
Sputum production
- Airway clearance
- Mucoactive drugs

Asthma and eosinophilia
- Inhaled corticosteroids

Low BMI
- Nutrition

GORD
- PPI
- +/– prokinetics

Other comorbidities
- Treat appropriately



Other factors
- Ethnic differences
- Environmental exposures
- Climatic variation
- Lifestyle
- Psychosocial

Targetable (endophenotypic) traits

Microbial (bacterial) dysbiosis
- Probiotics

Mycobiome (fungal) dysbiosis
- Antifungals

Neutrophil dysfunction
- Neutrophli elastase inhibitors

Protease-mediated lung damage
- Protease inhibitors

Ciliary dysfunction (primary or secondary)
- Airway clearance
- CFTR potentiator therapy

Systemic inflammation and vascular dysfunction
- Anti-inflammatory therapy

CFTR dysfunction
- CFTR potentiators
- CFTR correctors

Innate immune deficiency
- TLR-based therapeutics
- Antibiotic prophylaxis

James D Chalmers, Lancet Respir Med 2018; 6: 715–26

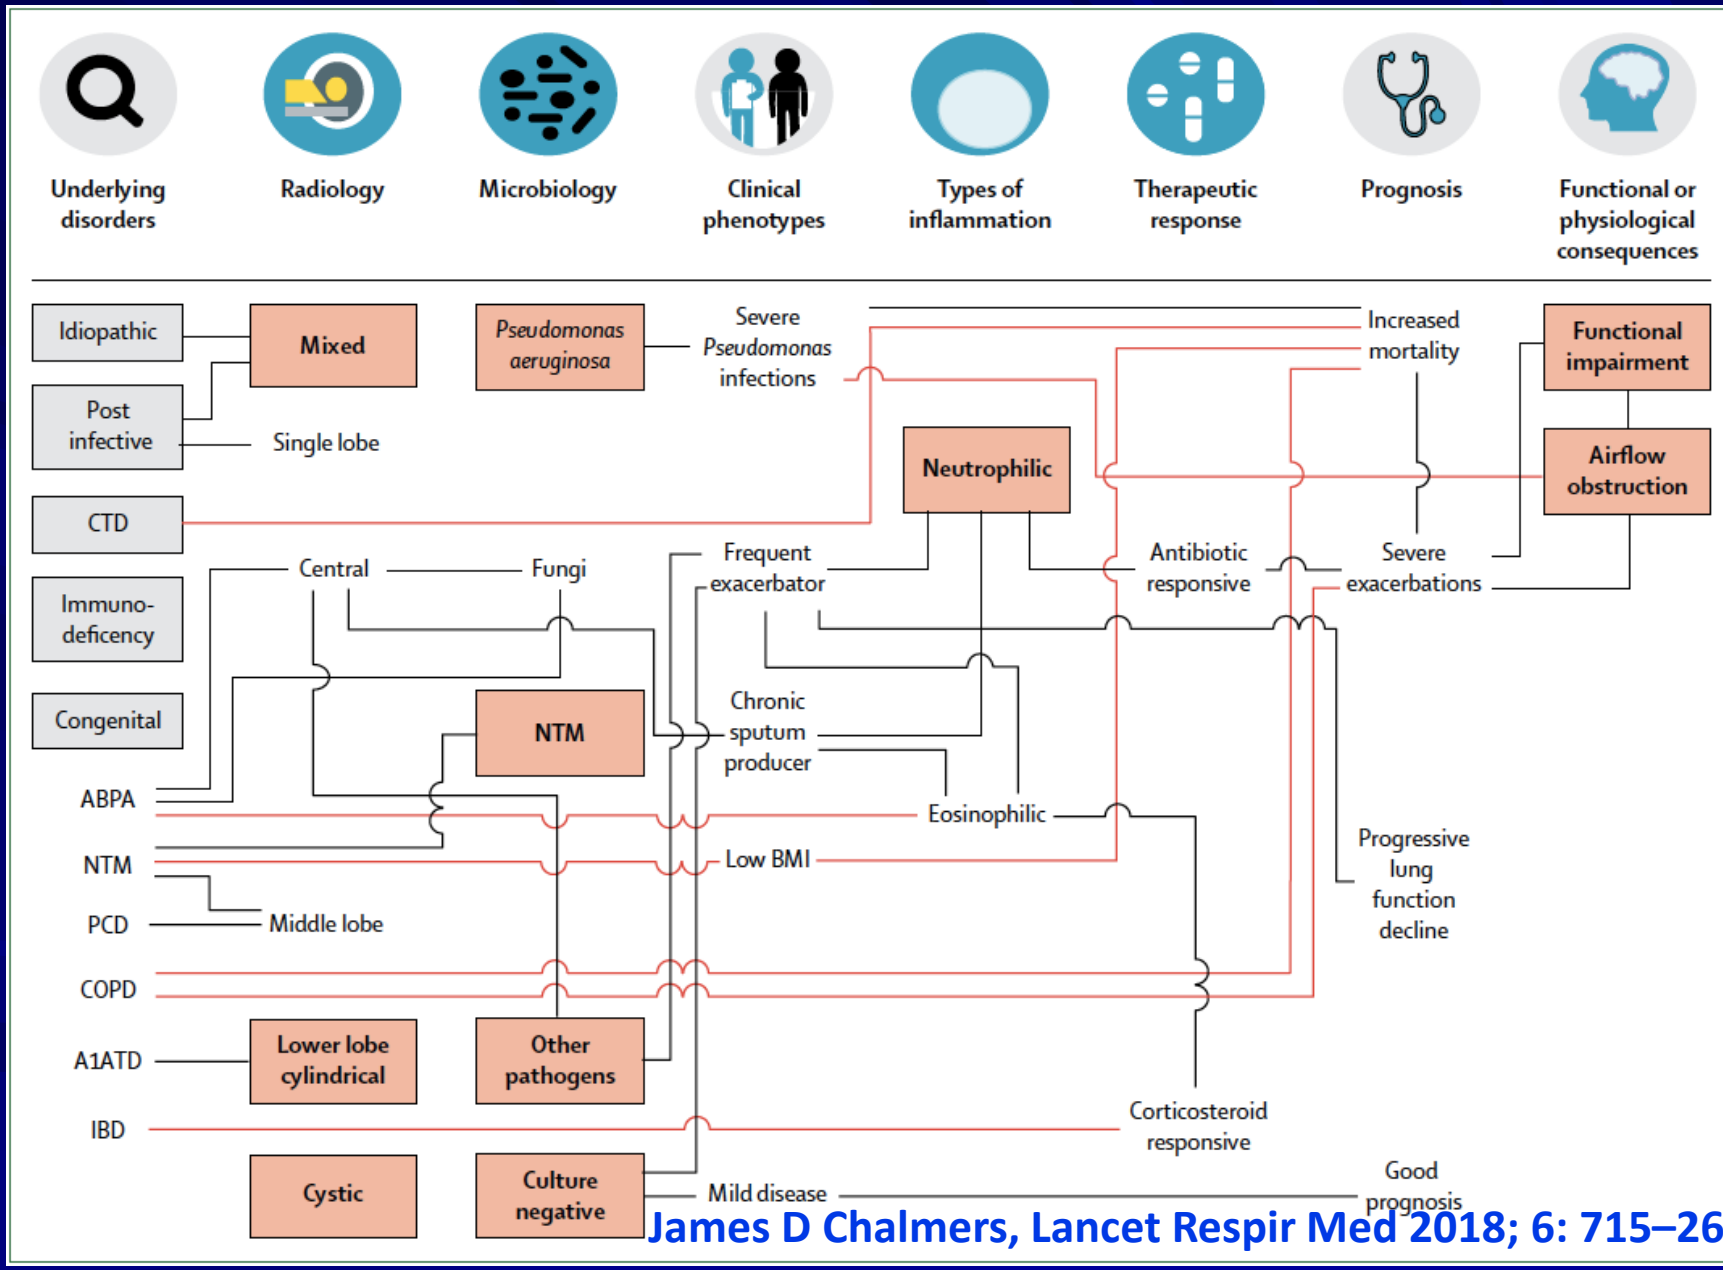
Outline

- Introduction
- The assessment of Non-Cystic Fibrosis Bronchiectasis (Non-CF BE)
- Management approach
- Summary

Summary

- Bronchiectasis is a heterogeneous disease of persist lung inflammation, interplay between immnogenetic susceptibility, immune dysregulation, bacterial infection and lung damage
- Two prognostic indices that aid clinical decisions are the bronchiectasis severity index (BSI) and the FACED score

Current classification of bronchiectasis



James D Chalmers, Lancet Respir Med 2018; 6: 715–26

Summary: Precision medicine

- Establishing the primary diagnosis is important, as it has implications for optimal management.
